

SAMSUNG C&T

Sensitivity analysis on Demand shifting capability based on the TwinHouse model

Kyunghun Woo, Senior Researcher,
Technology development team, Samsung C&T

Purpose of this study

- In the future heating demand shifting can do an important role in increasing the efficiency of the energy grid
 - Due to increasing portion of renewable energy and its fluctuating nature
 - Heating demand can be shifted for a while by intentional over heating when there is excess power generation in the grid

<Predicted Electricity demand and wind power generation in Denmark 2020>

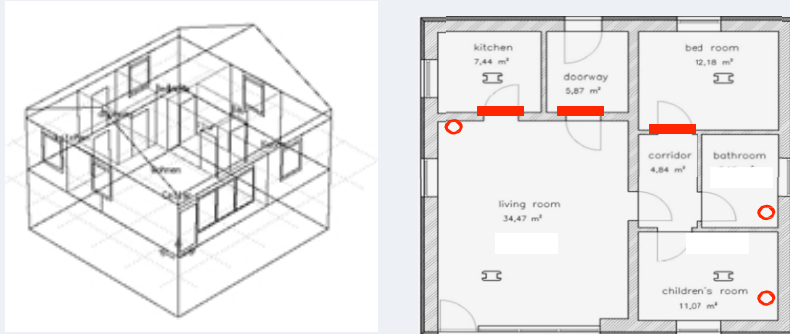

- Comprehensive sensitivity analysis is required to understand which factors are most important for the demand flexibility
 - There were a few sensitivity analysis on demand shifting but the number of parameters were very limited

Parameters which affect on demand shifting

1. Insulation level of building fabric (Wall, Floor, Ceiling, Window)
2. Amount of Thermal mass (All the part in a building)
3. Ventilation and Infiltration rate
4. Overheating duration time
5. Position of insulation (Exterior or interior insulation)
6. Solar radiation absorbed inside face of a building fabric
(G-value)
7. Types of heater
8. outside boundary condition of ceiling and floor of a floor

The TwinHouse Model

- Energy simulation model of the TwinHouse at the Fraunhofer test site in Holzkirchen, Germany is used for sensitivity analysis
 - The model is calibrated with real detailed measured data as an IEA Annex 58 activity

Item	Contents

Geometry, Calculation detail	<p>Same as TwinHouse calibrated Model</p>  <p>The image shows two representations of the TwinHouse model. On the left is a 3D wireframe diagram of a two-story house. On the right is a 2D floor plan with the following room areas: kitchen (7.44 m²), doorway (5.87 m²), bed room (12.18 m²), living room (34.47 m²), corridor (4.84 m²), bathroom, children's room (11.07 m²), and another bedroom area (11.07 m²). Red circles and lines highlight specific features on the floor plan.</p>
Construction Infiltration, Overheating duration time	Input Parameter of each cases
Climate Data	Copenhagen, Denmark
Simulation day and Time step	1 st of January, 2 minutes

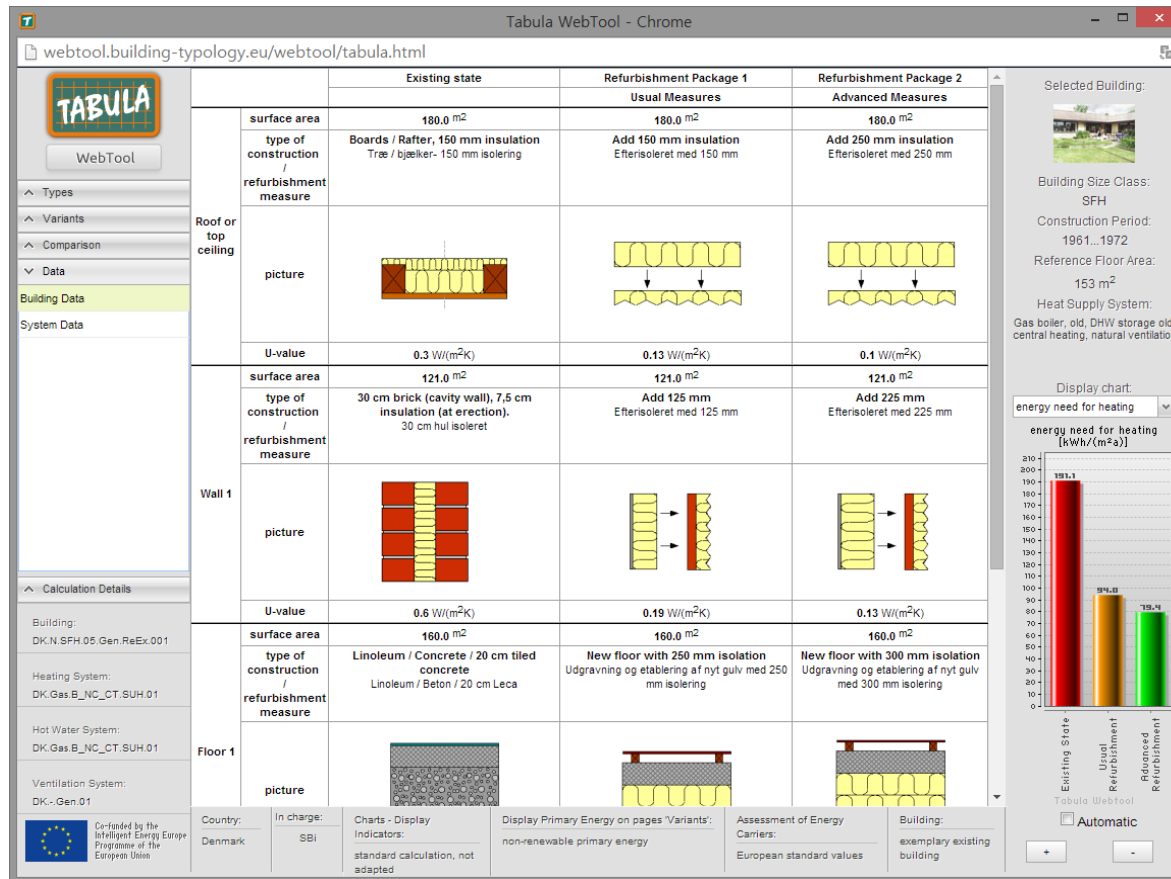

The TwinHouse Model

- Calibration to the simulation model include detailed thermal bridge analysis, change surface convection coefficient and ventilation heat losses adjustment
 - Calibrated model shows CC : 0.9611 and IC : 0.0516

Definition of parameter range

- Construction data is extracted from TABULA database

<Images from TABULA web tool>

Definition of parameter range

- Input for sensitivity analysis

Latin Hyper cubic sampling cases

- To reduce sampling cases while maintaining acceptable accuracy of statistical characteristics, Latin Hyper Cubic Sampling Method is used to generate sample cases
- Simlab 2.2 is used to generate 25 LHS samples which exceeds the minimum number of $3/2 \times 11$ (parameter number) = 16.5 which is recommended for LHS method

Table. 25 samples from SimLab

Simulation result and analysis of LHS cases

- Demand shifting time ranges from 6 to 142 minutes in each cases
 - Shortcoming of LHS method is that it is not easy to compare each cases and analyze the impact of each parameters because all the other parameter changes at the same time
- > Morris Method is used adapted to generate new sample cases

Morris Case sample cases

- Morris method is similar to LHS in that it uses even number of divided interval for each parameter. But in Morris method there is only 1 parameter change in each cases
 - Because of this characteristic it is easier to compare each results than LHS
- In Morris the number of model executions is computed as $r \cdot (k+1)$ where r is the level of sampling and k the number of model input factor
 - In total 72 simulation models were made

Morris Case sample cases

- Small values for μ to factors with negligible effect; σ measures the strength of the interaction effects
- Insulation level of construction and overheating time are ranked as the most important factor with overheating time
 - As seen in μ value the other factors do not have significant impact on the demand shifting time

Category	Item	Unit	μ	σ	Rank
insulation	wall	W/m ² k	49.33330	40.8444	2
	floor	W/m ² k	24.66670	24.1882	4
	ceiling	W/m ² k	9.33330	10.0133	5
	window	W/m ² k	52.00000	27.9428	1
g-value	window		1.33330	2.0656	10
Thermal mass	wall	(J/°C)	7.33330	14.4037	7
	floor	(J/°C)	0.00000	0	11
	ceiling	(J/°C)	8.66670	9.2664	6
infiltration		ac/h	5.33330	6.0222	9
Overheating time		hour	42.00000	39.5778	3
Position of Insulation			7.33330	7.7632	7

Findings through Morris case study

- Same thermal mass and different insulation type
 - Due to slow response of exterior insulated wall to the change in the indoor temperature, at the end of the overheating time there is more heat loss through convection to surface
 - So the saturation time is reduced

Case	Wallins	Floorins	Ceilins	Win Uvalue	gvalue	Wall Thermalmass	Floor TMass	Ceil TMass	Infiltration	Insulation Type	Overheating Time	Demand shifting time
3	1.64242	0.481663	0.48045	0.8	0.85	419634	95613.7	56113.2	0.224406	1	2	106
4	1.64242	0.481663	0.48045	0.8	0.85	419634	95613.7	56113.2	0.224406	3	2	96

Findings through Morris case study

- Same U-value and different Thermal Mass
 - in case 70 which has interior insulation there is a decrease in demand shifting time by 18min when the wall thermal mass is increased by 73%

Case	Wallins	Floorins	Ceilins	Win Uvalue	gvalue	Wall Thermalmass	Floor TMass	Ceil TMass	Infiltration	Insulation Type	Overheating Time	Demand shifting time
69	1.90334	0.683653	0.751639	0.8	0.63	327205	437449	122469	0.155399	1	2	62
70	1.90334	0.683653	0.751639	0.8	0.63	567622	437449	122469	0.155399	1	2	44

- During daytime when the ambient temperature rise, surface temperature of Case 69 which has less thermal mass rise faster than case70, which cause more conduction heat losses in Case70.
- Even the relatively higher U-value of these two cases promotes conduction heat loss with small differences in outside surface temperature

Findings through Morris case study

- Same U-value and different Thermal Mass

Findings through Morris case study

- Overheating time
 - In a few cases there was a decrease in demand shifting time when there was an increase in overheating time and vice versa

Case	Wallins	Floorins	Ceilins	Win Uvalue	gvalue	Wall Thermalmass	Floor TMass	Ceil TMass	Infiltration	Insulation Type	Overheating Time	Demand shifting time
11	0.69492	0.481663	0.48045	2.7	0.63	672599	255067	101363	0.102399	3	2	98
12	0.69492	0.481663	0.48045	2.7	0.63	672599	255067	101363	0.102399	3	4	42

- It is sure that thermal mass absorb more heat as the overheating time gets longer.
- But as in these cases if the end of overheating time goes over outdoor peak temperature time, there happens more heat losses through exterior wall which is the most important factors in demand shifting
- So to get the best demand shifting time, ambient environment should also be taken into account

Conclusion

- High Insulation of a building is most important factor in demand shifting capability of the building type
- As long as a building is built within the parameter range in TABULA database , thermal mass is not an important factor in demand shifting
- If overheating time is not enough to heat up the thermal mass of a wall construction, interior insulation is more suitable to get an optimal performance in demand shifting
- The time of a day for overheating also have important factors to increase saturation time
- To get best demand shifting capability, detailed analysis on various building stock within the grid needs to be carried out

Thank you for your attention
